

The Rule of Four

There are 4 equivalent descriptions of a Function:

Narrative	Data Set	Graph	Equation												
	<table border="1"> <thead> <tr> <th>x</th> <th>y</th> </tr> </thead> <tbody> <tr><td>1</td><td>-7</td></tr> <tr><td>2</td><td>5</td></tr> <tr><td>3</td><td>2</td></tr> <tr><td>4</td><td>5</td></tr> <tr><td>5</td><td>1</td></tr> </tbody> </table>	x	y	1	-7	2	5	3	2	4	5	5	1		$y = f(x)$ $y = \frac{ax + b}{cx - d}$
x	y														
1	-7														
2	5														
3	2														
4	5														
5	1														

To be or not to be a Function

Let  $x$  (input) = ID Number and  $y$  (output) = date of birth (DOB). Although 2 different people can have the same DOB, this is a function because each person ( $x$ ) has exactly one DOB ( $y$ ). The Domain = {all ID numbers}

Let  $x$  (input) = ID Number and  $y$  (output) = GPA. At this exact moment, this would be a function. However, over time, this would not be a function because a single person ( $x$ ) could have multiple GPA's ( $y$ ).

Let  $x$  (input) = License plate number and  $y$  (output) = VIN. We would expect this is a function because each vehicle ( $x$ ) has exactly one VIN( $y$ ). Domain = {all License Plate numbers}

Let  $x$  (input) = License plate number and  $y$  (output) = odometer reading. We would expect this is not a function because a vehicle ( $x$ ) could have different readings ( $y$ ) once driving occurred.

Let  $x$  (input) = time during today and  $y$  (output) = temperature at a specific location. We would expect this is a function because at each point in time, there should be exactly one temperature reading ( $y$ ). Domain = {all times:  $0:00 \leq x < 24:00$ }

Let  $x$  (input) = sq-ft of room painted and  $y$  (output) = amount of paint used. This should be a function because each sq-ft ( $x$ ) should require the same amount of paint ( $y$ ). Domain:  $\{0 \leq x \leq \text{room's total sq-ft}\}$

Data Set		Data Set																									
<table border="1"> <thead> <tr> <th>x</th> <th>y</th> </tr> </thead> <tbody> <tr><td>1</td><td>9.36</td></tr> <tr><td>2</td><td>4.81</td></tr> <tr><td>3</td><td>4.81</td></tr> <tr><td>1</td><td>9.36</td></tr> <tr><td>5</td><td>8.70</td></tr> </tbody> </table>	x	y	1	9.36	2	4.81	3	4.81	1	9.36	5	8.70	This data set is a <u>function</u> because for each $x$ , there is exactly one $y$ . It's OK that for $x = 2,3$ the $y$ 's are the same.	<table border="1"> <thead> <tr> <th>x</th> <th>y</th> </tr> </thead> <tbody> <tr><td>1</td><td>9.36</td></tr> <tr><td>2</td><td>6.40</td></tr> <tr><td>3</td><td>4.81</td></tr> <tr><td>4</td><td>9.36</td></tr> <tr><td>4</td><td>8.70</td></tr> </tbody> </table>	x	y	1	9.36	2	6.40	3	4.81	4	9.36	4	8.70	This data set is <u>not a function</u> because for $x = 4$ , there are two different $y$ -values.
x	y																										
1	9.36																										
2	4.81																										
3	4.81																										
1	9.36																										
5	8.70																										
x	y																										
1	9.36																										
2	6.40																										
3	4.81																										
4	9.36																										
4	8.70																										

Graph	Graph
<p>This graph is a <u>function</u> because it passes the vertical line test (VLT). Domain = <math>\{ -6 &lt; x \leq 7 \}</math></p>	<p>This data set is <u>not a function</u> because it does not pass the vertical line test (VLT)</p>

Equation

$5y = 3x + 4$	<p>This is a <u>function</u> because it can be legitimately entered into the form <math>y = f(x)</math>.</p>
$5y^2 = 3x + 4$	<p>This is <u>not a function</u> because it when solved for 'y' we get the form <math>y = \pm \sqrt{\frac{3x + 4}{5}}</math>. Hence there are two y-values for many x-values.</p>
